Modulation of Coffee Flavour Precursor Levels in Green Coffee Grains

Background of the Invention:

5

Coffee contains a highly complex mixture of flavour molecules. Extensive research on the composition of instant and fresh ground coffee beverages has, to date, identified more than 850 compounds, many of which are flavour active molecules (Flament, I (2002) *Coffee Flavor Chemistry*, John Wiley and Sons, UK). However, few of the final coffee flavour molecules found in the cup are present in the raw material, the green grain (green beans) of the plant species *Coffea arabica* or *Coffea canephora (robusta)*. In fact, the majority of the coffee flavour compounds are generated during one or more of the multiple processing steps that occur from the harvest of the ripe red coffee cherries to the final roasted ground coffee product, or extracts thereof, for example soluble coffee products.

10

The various steps in the production of coffee are described in Smith, A.W., in *Coffee; Volume 1: Chemistry* pp 1-41, Clark, R.J. and Macrea, R. eds, Elsevier Applied Science London and New York, 1985; Clarke, R.J., in *Coffee: Botany, Biochemistry, and Production of Beans and Beverage*, pp 230-250 and pp 375-393; and Clifford, M.N. and Willson, K.C.

20

eds, Croom Helm Ltd, London. Briefly, the process starts with the collection of mature, ripe red cherries. The outer layer, or pericarp, can then be removed using either the dry or wet process. The dry process is the simplest and involves 1) classification and washing of the cherries, 2) drying the cherries after grading (either air drying or mechanical drying), and 3) dehusking the dried cherries to remove the dried pericarp. The wet process is slightly more complicated, and generally leads to the production of higher quality green beans. The wet process is more often associated with *C. arabica* cherries. The wet process consists of 1)

25

classification of the cherries, 2) pulping of the cherries, this step is done soon after harvest and generally involves mechanical removal of the "pulp", or pericarp, of the mature cherries, 3) "fermentation", the mucilage that remains attached to the grain of the cherries after

30

pulping is removed by allowing the grain plus attached mucilage to be incubated with water in tanks using a batch process. The "fermentation" process is allowed to continue up to 80 hours, although often 24 hours is generally enough to allow an acceptable fermentation and to cause the pH to drop from around 6.8-6.9 to 4.2-4.6, due to various enzymatic activities and the metabolic action of microorganisms which grow during the fermentation, 4) drying, this

step involves either air or mechanical hot air drying of the fermented coffee grain and 5) “hulling”, this step involves the mechanical removal of the “parch” of the dried coffee grain (dried parchment coffee) and often the silverskin is also removed at this stage. After wet or dry processing, the resulting green coffee grain are often sorted, with most sorting procedures 5 being based on grain size and/or shape.

The next step in coffee processing is the roasting of the green grain after dehusking or dehulling of dry or wet processed coffee, respectively. This is a time-dependent process which induces significant chemical changes in the bean. The first phase of roasting occurs 10 when the supplied heat drives out the remaining water in the grain. When the bulk of the water is gone, roasting proper starts as the temperature rises towards 190-200°C. The degree of roasting, which is usually monitored by the colour development of the beans, plays a major role in determining the flavour characteristics of the final beverage product. Thus, the time and temperature of the roasting are tightly controlled in order to achieve the desired coffee 15 flavour profile. After roasting, the coffee is ground to facilitate extraction during the production of the coffee beverage or coffee extracts (the latter to be used to produce instant coffee products). Again, the type of grinding can influence the final flavour of the beverage.

While a considerable amount of research has been carried out on the identification of the 20 flavour molecules in coffee, much less work has been done regarding the physical and chemical reactions which occur within the coffee grains during each of the processing steps. This latter point is particularly evident for the roasting reaction, where the large number of grain constituents undergo an extremely complex series of heat induced reactions (Homma, S. 2001, In “Coffee: Recent Developments”. R.J. Clarke and O.G. Vitzthum eds, Blackwell 25 Science, London; Yeretzian, C., *et al* ((2002) Eur. Food Res. Technol. 214, 92-104; Flament, I (2002) Coffee Flavor Chemistry, John Wiley and Sons, UK; Reineccius, G.A., “The Maillard Reaction and Coffee Flavor” Conference Proceedings of ASIC, 16th Colloque, Kyoto, Japan 1995). Because of the large number of the potential reactants, and the complexity of the reactions involved, little research data currently exist which establishes 30 strong links between specific biological molecules present in the green beans and the numerous flavour molecules identified in a cup of coffee.

Nonetheless, while the details of most of the reactions that occur during the different steps of coffee processing remain relatively unclear, it is thought that an important flavour generating

reaction responsible for many of the flavours associated with coffee aroma is the "Maillard" reaction during coffee roasting. A vigorous Maillard reaction occurs between the grain reducing sugars/polysaccharide degradation products and the amino group containing molecules (particularly the proteins, peptides, and amino acids) during the roasting step.

5

Because the Maillard reaction apparently makes an important contribution to the generation of coffee flavour and aroma molecules during coffee roasting, there might be an association between the levels of primary Maillard reactants in the green beans and the quality of the flavour/aroma developed after roasting.

10

As noted above, an important group of substrates in the Maillard reaction are the amino acids, peptides and proteins. To date, there are no firm associations between the levels, or types, of amino group containing molecules in different coffees and the qualities of those coffees.

Although the amino acid contents of *arabica* and *robusta* coffee beans have been analysed

15

(M.N. Clifford 1985, In "Coffee: Botany, Biochemistry, and Production of Beans and Beverage", Clifford and Willson eds, Croom Helm London; Arnold *et al* 1996, Z. Lebensm Unters Forsch., Vol 199, 22-25; Ludwig *et al* 2000, Eur. Food Res Technol., Vol 211, 111-116.), there are no reports directly linking specific levels or ratios of amino acids and high or low flavour qualities. Using 2-D electrophoresis, it has been shown that differences exist in

20

the levels and amounts of the major storage proteins in *arabica* and *robusta* green coffee beans – however, no association between these storage protein differences and flavour quality was noted (Rogers *et al*, 1999, Plant Physiol. Biochem. Vol 37, 261-272). It has also recently been found that small differences exist between the storage proteins of immature and mature coffee beans, which have different flavour qualities (Montavon, P. *et al*, 2003, J. Agric and

25

Food Chemistry Vol 51, 2328-2334). However, because there are many changes occurring during seed maturation, this latter work only suggests a link may exist between the quality improvement caused by maturation and the differences seen in the 2-D gel patterns of the main coffee storage proteins. Overall, currently no clear evidence exists linking any differences seen for the coffee storage proteins, or other major green bean proteins, and the flavour qualities of coffee.

30

It has recently been shown that there are differences in the profiles of peptides isolated from *arabica* and *robusta* green beans (Ludwig *et al* 2000, Eur. Food Res Technol., Vol 211, 111-116.). Although their results showed that the *arabica* and *robusta* peptide extracts differ in

their aroma precursor profile, the data presented in this report do not identify which component(s) in the extracts is / are responsible for these aroma profile differences. These workers also detected at least two different proteinase activities in crude extracts of the green coffee, but they did not correlate any specific activities with aroma/flavour quality (Ludwig *et al* 2000, Eur. Food Res Technol., Vol 211, 111-116). Finally, it is also thought that the very high temperatures used during the later stages of green coffee grain roasting cause substantial cleavage of the proteins present in the coffee grain (Homma, S. 2001, In "Coffee: Recent Developments". R.J. Clarke and O.G. Vitzthum eds, Blackwell Science, London; Montavon, P., *et al* 2003, "Changes in green coffee protein profiles during roasting", J. Agric. Food Chem. 51, 2335-2343). However, the overall scheme for this protein degradation is very poorly understood, but presumably depends on, among other things, the precise state of the main coffee proteins in the raw material before the start of roasting. To our knowledge, there are no other significant reports addressing the possibility that peptide profiles in coffee could be involved in the production of coffee aroma/flavour.

In the roasting of the fermented seeds of *Theobroma cacao* (cocoa beans), there would appear to be an involvement of seed amino acids and peptides in the development of Maillard reaction aromas/flavours. Relative to other seeds, *T. cacao* seeds have been shown to have an unusually high level of aspartic proteinase activity (Biehl, B., Voigt, J., Voigt, G., Heinrichs, H., Senyuk, V. and Bytof, G. (1994) "pH dependent enzymatic formation of oligopeptides and amino acids, the aroma precursors in raw cocoa beans". In *The Proceedings of the 11th International Cocoa Research Conference*, 18-24 July 1993, Yamoussoukro, Ivory Coast). In order to produce cocoa beans with a high level of cocoa flavour precursors, it is necessary to carry out a natural fermentation step (unfermented beans develop little flavour when roasted). During this fermentation step, the sugars in the pulp are fermented, generating high levels of acids, particularly acetic acid (Carr, J.G. (1982) *Cocoa*. In *Fermented Foods. Economic Microbiology*. Vol 7. pages 275-292. (A.H. Rose ed). Academic Press). As the fermentation continues, the pH in the seed decreases and the cell structure becomes disrupted. The low pH triggers the abundant cacao seed aspartic proteinase to become mobilized and/or activated, resulting in a massive degradation of cellular protein (Biehl, B., Passern, D., and Sagemann, W. (1982) "Effect of Acetic Acid on Subcellular Structures of Cocoa Bean Cotyledons". J. Sci. Food Agric. 33, 1101-1109; Biehl, B., Brunner, E., Passern, D., Quesnel, V.C., and Adomako, D. (1985) "Acidification, proteolysis and flavour potential in fermenting cocoa beans". J. Sci. Food Agric. 36, 583-598). Peptides and amino acids have

been shown to be cocoa flavour precursors (Rohan, T. (1964) "The precursors of chocolate aroma: a comparative study of fermented and unfermented cocoa beans". J. Food Sci., 29, 456-459; Voigt, J. and Biehl, B. (1995) "Precursors of the cocoa specific aroma components are derived from the vicilin-class (7S) globulin of the cocoa seeds by proteolytic processing".
5 Bot. Acta 108, 283-289). Thus, the *T. cacao* seed aspartic proteinase, together with a seed serine carboxypeptidase, have been proposed to be critical for the generation of cocoa flavour precursors during fermentation (Voigt, J. and Biehl, B. (1995) "Precursors of the cocoa specific aroma components are derived from the vicilin-class (7S) globulin of the cocoa seeds by proteolytic processing". Bot. Acta 108, 283-289; Voigt, J., Heinrichs, H., Voigt, G. and
10 Biehl, B. (1994) "Cocoa-specific aroma precursors are generated by proteolytic digestion of the vicilin-like globulin of cocoa seeds". Food Chemistry, 50, 177-184.) The gene encoding the abundant cacao seed aspartic proteinase has been identified and a method to over-express this protein in cacao seeds which can generate increased levels of cacao flavour precursor amino acids and peptides in fermented cocoa beans has recently been described in
15 International Patent Publication No. 02/04617, the whole contents of which are incorporated herein by reference. However, the teaching of International Patent Publication No. 02/04617 is directed towards cacao seeds, which undergo a specific long acid fermentation step, unlike coffee grains which do not.

20 Objects of the Invention

It is an object of the present invention to improve the flavour quality of coffee.

More specifically, it is an object of the present invention to improve the levels of the flavour
25 precursors in the raw material (the green grain) so that, following post harvest treatment and roast-processing, an improved flavour is achieved. Without being bound by theory, it is believed that, if there are variations in the levels of peptides and protein degradation between coffees with significantly different flavours, then it is possible that these variations could be due to differences in the endogenous proteinase activities in these different grains. This
30 difference might be detectable at the level of mRNA expression by variations in the levels of expression for particular seed proteinase genes.

Statements of the Invention

The present invention involves, therefore, identifying gene sequences encoding for coffee grain (seed) specific proteinases and showing that there are indeed variations in the expression of these genes in *arabica* and *robusta*.

5 More specifically, the present invention discloses a major coffee cysteine proteinase (CcCP-1), a major coffee cysteine proteinase inhibitor (CcCPI-1) and coffee aspartic proteinases (CcAP-1 and CcAP-2), all of which are expressed in coffee seeds. We further show how either over-expression of these proteins specifically late in seed development, or the reduced expression of these proteins during late seed development, can alter the amino

10 acid/peptide/protein profile of the mature beans. By using one or more of the disclosed gene sequences and gene constructs to alter the amino acid/peptide/protein profile of the mature beans, we disclose a new method to alter the flavour precursor profile of mature coffee beans, and thus thereby allow the production of roasted coffee beans with altered flavours.

15 In a first aspect, the present invention provides an isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having cysteine proteinase activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 2 have at least 70%, preferably at least 80%, sequence identity based on the ClustalW alignment method; or the complement of the nucleotide sequence, wherein the complement contains the

20 same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary. Preferably, the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 2 have at least 85%, preferably at least 90%, optionally at least 95%, sequence identity based on the ClustalW alignment method. Preferably, the nucleotide sequence comprises the nucleotide sequence of SEQ ID

25 No. 1. Preferably, the polypeptide comprises the amino acid sequence of SEQ ID No. 2.

In a second aspect, there is provided an isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having cysteine proteinase inhibitor activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 4 have at least 70%, preferably at least 80%, sequence identity based on the ClustalW alignment method; or the complement of the nucleotide sequence, wherein the complement contains the same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary. Preferably, the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 4 have at least 85%, preferably at

least 90%, optionally at least 95%, sequence identity based on the ClustalW alignment method. Preferably, the nucleotide sequence comprises the nucleotide sequence of SEQ ID No. 3. Preferably, the polypeptide comprises the amino acid sequence of SEQ ID No. 4.

- 5 In a third aspect, there is provided an isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having aspartic endoproteinase activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence selected from SEQ ID No. 6 or 8, preferably SEQ ID No. 8, have at least 75%, preferably at least 80%, sequence identity based on the ClustalW alignment method, or the complement of the nucleotide sequence,
- 10 wherein the complement contains the same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary. Preferably, the amino acid sequence of the polypeptide and the amino acid sequence selected from SEQ ID No. 6 or 8, preferably SEQ ID No. 8, have at least 85%, preferably at least 90%, optionally at least 95%, sequence identity based on the ClustalW alignment method. Preferably, the
- 15 nucleotide sequence comprises the nucleotide sequence of SEQ ID No. 5 or 7, preferably SEQ ID No. 7. Preferably, the polypeptide comprises the amino acid sequence of SEQ ID No. 6 or 8, preferably SEQ ID No. 8.

In a further aspect, there is provided a vector comprising the polynucleotide of any one of first to third aspects of the invention.

In a further aspect, there is provided a recombinant DNA construct comprising the polynucleotide of any one of first to third aspects of the invention, operably linked to a regulatory sequence.

25 In a further aspect, there is provided a method for transforming a cell comprising transforming the cell with the polynucleotide of any one of first to third aspects of the present invention.

30 In a further aspect, there is provided a cell comprising the aforementioned recombinant DNA construct, which cell is preferably a prokaryotic cell, an eukaryotic cell or a plant cell, preferably a coffee cell.

In a further aspect, there is provided a transgenic plant comprising such a transformed cell.

In the present application, coffee cherry terms are defined as follows: coffee cherry; entire fruit; exocarp, skin; pericarp, fleshy major outer layer of cherry; and grain, coffee seed. For a fuller explanation of these terms, reference is made to Clarke, R.J., in Coffee: Botany, Biochemistry, and Production of Beans and Beverage, pp 230, Clifford, M.N. and Willson, K.C. eds, Croom Helm Ltd, London, the contents of which are incorporated in their entirety.

5

Brief Description of the Invention

10 The invention can be understood from the following detailed description and the accompanying Sequence Listing which forms part of the present application.

Table 1 hereunder lists the polypeptides that are described herein, along with the corresponding sequence identifier (SEQ ID No) as used in the attached listing.

15

Table 1:

SEQ ID No 1 (CcCP1 : Cysteine proteinase, nucleic acid and its corresponding amino acid)

SEQ ID No 2 (CcCP1: Cysteine proteinase, amino acid)

20 SEQ ID No 3 (CcCPI-1 : Cysteine proteinase Inhibitor, nucleic acid and its corresponding amino acid)

SEQ ID No 4 (CcCPI-1: Cysteine proteinase Inhibitor, amino acid)

SEQ ID No 5 (CcAP1 : Aspartic endoproteinase 1, nucleic acid and its corresponding amino acid)

25 SEQ ID No 6 (CcAP1 : Aspartic endoproteinase 1, amino acid)

SEQ ID No 7 (CcAP2 : Aspartic proteinase 2, nucleic acid and its corresponding amino acid)

SEQ ID No 8 (CcAP2 : Aspartic proteinase 2, amino acid)

30 The sequence listing employs the one letter codes for nucleotide sequence characters and the three letter codes for amino acids as defined for IUPAC-IUBMB Standards and as described in Nucleic Acids Research 13:3021-3030 (1985), which is incorporated herein by reference.

Drawings

In the drawings,

5 **Figure 1** shows a Northern blot analysis of cysteine proteinase gene in different tissues of *Coffea arabica*, in which the lanes are labeled R: root, S: stem, L: young leaves; and SG, LG, Y and Red are grain from small green fruit, large green fruit, yellow fruit and red fruit, respectively. Five micrograms of total RNA was loaded in each lane. MW is an RNA size ladder. Panel A illustrates an autoradiography after 24 hours exposure and Panel B
10 demonstrates the ethidium bromide staining of the gels prior to blotting;

15 **Figure 2** shows a Northern blot analysis of Cysteine proteinase inhibitor gene in different tissues of *Coffea arabica*, in which the lanes are labeled R: root, S: stem, L: young leaves and SG, LG, Y and Red for grain from small green fruit, large green fruit, yellow fruit and red fruit, respectively. Five micrograms of total RNA was loaded in each lane. MW is an RNA size ladder. Panel A illustrates an autoradiography after 24 hours exposure and panel B demonstrates the ethidium bromide staining of the gels prior to blotting;

20 **Figure 3** shows a Northern blot analysis of Cysteine proteinase inhibitor gene in different stages of development of *Coffea arabica* (ARA) and *Coffea robusta* (ROB) fruit. The lanes are labeled small green fruit (SG), large green fruit (LG), yellow fruit (Y) and red fruit (Red), respectively. Five micrograms of total RNA was loaded in each lane. MW is an RNA size ladder. Panel A illustrates an autoradiography after 24 hours exposure. Panel B demonstrates the ethidium bromide staining of the gels prior to blotting; and
25

Figure 4 shows a Northern blot analysis of aspartic proteinase 2 (CcAP2) gene in different tissues of *Coffea arabica*, in which the lanes are labelled R: root, S: stem, L: young leaves, F: flowers; SG(G) and (P), LG(G) and (P), Y(G) and (P) and Red(G) and (P) are for grain and for pericarp, respectively, from small green, large green, yellow and red cherries, and SG(G),
5 LG(G), Y(G) and R(G) for pericarp from small green, large green, yellow and red cherries respectively. Five micrograms of total RNA was loaded in each lane. Panel A demonstrates the ethidium bromide staining of large ribosomal RNA prior to blotting as a loading control and panel B is an autoradiogram showing the appearance of the CcAP2 mRNA in the specific tissues tested.

10

Detailed Description of the Invention

As used herein, a “polynucleotide” is a nucleotide sequence such as a nucleic acid fragment. A polynucleotide may be a polymer of RNA or DNA that is single- or double-stranded, that
15 optionally contains synthetic, non-natural or altered nucleotide bases. A polynucleotide in the form of a polymer of DNA may comprise one or more segments of cDNA, genomic DNA, synthetic DNA or mixtures thereof.

Similar nucleic acid fragments are characterised, in the present invention, by the percent
20 identity of the amino acid sequences that they encode, to the amino acid sequences disclosed herein, as determined by algorithms commonly used by those skilled in the art. Suitable nucleic acid fragments (or isolated polynucleotides of the first to third aspects of the present invention) encode polypeptides that are at least 70% identical, preferably at least 80% identical, to the amino acid sequences disclosed herein. Preferred nucleic acid fragments
25 encode amino acid sequences that are at least 85% identical to the amino acid sequences disclosed herein. More preferred nucleic acid fragments encode amino acid sequences that are at least 90% identical to the amino acid sequences disclosed herein. Still more preferred are nucleic acid fragments that encode amino acid sequences that are at least 95% identical to the amino acid sequences disclosed herein. Multiple alignment of sequences should be
30 performed using the ClustalW method of alignment (Thompson *et al*, 1994, Nucleic Acids Research, Vol 22, p4673-4680; Higgins & Sharp 1989 Cabios. 5:151-153).

As used herein, the term “similar nucleic acid fragments” refers to polynucleotide sequences in which changes in one or more nucleotide bases result in substitution of one or more amino

acids, but which changes either do not affect the function of the polypeptide encoded by the nucleotide sequence or do not affect the ability of nucleic acid fragment to mediate gene expression by gene silencing via, for example, antisense or co-expression technology. The term "similar nucleic acid fragments" also refers to modified polynucleotide sequences, in
5 which one or more nucleotide bases is / are deleted or inserted, provided that the modifications do either do not affect the function of the polypeptide encoded by the nucleotide sequence or do not affect the ability of nucleic acid fragment to mediate gene expression by gene silencing. It will, therefore, be understood that the scope of the present invention extends beyond the polynucleotide and polypeptide sequences specifically
10 disclosed herein.

Similar nucleic acid fragments may be selected by screening nucleic acid fragments in the form of subfragments or modified nucleic acid fragments, for their ability to affect the level of the polypeptide encoded by the unmodified nucleic acid fragments in the plant or plant
15 cell.

The term "operably linked" refers to the association of two or more nucleic acid fragments on a single nucleic acid fragment so that the function of one is affected by the other.

"Regulatory sequences" refer to nucleotide sequences located upstream, within, or

20 downstream, of a coding sequence and which influence transcription, RNA processing or stability, or translation of the coding sequence associated therewith. Regulatory sequences may include promoters, translation leader sequences, introns and polyadenylation recognition sequences. When a regulatory sequence in the form of a promoter is operably linked to a coding sequence, the regulatory sequence is capable of affecting the expression of the coding
25 sequence. Coding sequences can be operably linked to regulatory sequences in sense or antisense orientation.

The term "expression" refers to the transcription, and stable accumulation, of sense RNA (mRNA) or antisense RNA derived from the nucleic acid fragments of the present invention.

30 Expression may also refer to the translation of mRNA into a polypeptide. Overexpression refers to the production of a gene product in a transgenic cell, that exceeds the level of production in normal, or non-transformed, cells. "Altered levels" refers to the production of gene product(s) in a transgenic cell in amounts or proportions that differ from that of normal, or non-transformed, cells.

“Transformation” refers to the transfer of a nucleic acid fragment into the genome of a host cell, resulting in genetically stable inheritance. Host cells containing the transformed nucleic acid fragments are referred to herein as “transgenic cells.

5

Standard recombinant DNA and molecular cloning techniques as used herein are well known in the art and are described more fully in Sambrook *et al* "Molecular Cloning: A Laboratory Manual"; Cold Spring Harbor Laboratory Press: Cold Spring Harbor, 1989, which is incorporated herein by reference.

10

Examples

The following Examples illustrate the invention without limiting the invention to the same. In the examples, all parts and percentages are by weight and degrees are in Celsius, unless 15 this is otherwise specified.

In the following Examples, these abbreviations have been used:

PCR : Polymerase chain reaction

RACE : Rapid amplification cDNA ends

20

From the above discussion and the Examples below, those skilled in the art can ascertain the essential features of the present invention, and without departing from the scope thereof can make various changes and modifications thereto, to adapt it to various usages and conditions as desired.

25

Production of cDNA libraries and screening

Production of Seed Specific RNA

Coffee cherries of the *Robusta* variety Q121 were harvested 30 WAF (weeks after flowering) 30 at the ICCRI, Indonesia. The pericarps of these cherries were then removed and the remaining perisperm/endosperm material was frozen and ground to a powder in liquid nitrogen. The RNA was extracted from the frozen powder material using the method described previously for the RNA extraction of cacao seeds (Guilloteau, M. *et al*, 2003, Oil bodies in *Theobroma cacao* seeds: cloning and characterisation of cDNA encoding the 15.8

and 16.9 kDa oleosins. Plant Science Vol 164, 597-606). Poly A⁺ RNA was prepared from approximately 250µg total RNA using the "PolyA Purist™" kit of AMBION (manufactured by Ambion, Inc.) according to their kit instructions.

5 *Production of First Set of Seed cDNA clones*

Approximately 50-100ng of this poly A⁺ RNA was then employed in the synthesis of the first strand cDNA using "SuperScript™ II RNase H⁻ reverse transcriptase (GIBCOBRL™) and the SMART™ PCR cDNA synthesis kit (Clontech) as follows. A reaction containing 2µl of 30 WAF poly A⁺ RNA, 1 µL CDS oligo (SMART™ PCR cDNA kit, Clontech), 1 µL Smart II oligo (SMART™ PCR cDNA kit, Clontech), and 8 µL deionised H₂O. This mixture was heated to 72°C for 5 minutes and then placed on ice. Then the following was added; 1 µL 10 mM dNTPs, 4 µL SuperScriptII™ 1st stand buffer and 2 µL DTT. This mixture was put at 42°C for 2 minutes then 1 µL of SuperScriptII™ RNaseH⁻ reverse transcriptase (200 units/µL GIBCO BRL™) was added and the mixture was incubated in an air circulating incubator at 42°C for a further 50 minutes.

After the reverse transcription reaction, the following PCR reaction was carried out. 98 µL of the Master Mix described in the SMART™ PCR cDNA kit (Clontech) containing Advantage™ 2 polymerase (Advantage™ 2 PCR kit, ClonTech) was set up on ice and then 3 µL of the 1st strand cDNA synthesis reaction described above was added. This 100 µL PCR reaction was then placed in a MJ Research PTC-150 HB apparatus and the following PCR conditions were run: 95°C for 1 minute, then 16 cycles of 95°C for 15 seconds, 65°C for 30 seconds, 68°C for 6 minutes. The amplified DNA was purified using the Strataprep™ PCR Purification Kit (Stratagene) according to the suppliers' instructions. The DNA, which was eluted in 50 µL deionized water, was then "polished" using the Pfu-1 polymerase reagents contained in the PCR-Script™ Amp cloning kit (Stratagene) as follows; 50 µL DNA, 5 µL 10 mM dNTPs, 6.5 µL 10 x Pfu-1 polishing buffer, 5 µL cloned Pfu-1 DNA polymerase (0.5 U/µL). This reaction was then incubated at 72°C for 30 minutes in a PCR apparatus with a heated cover (Perkin Elmer). Using the protocol described in the pPCR-Script™ Amp kit (Stratagene), the polished (blunted) PCR products were ligated into the Srf-1 digested pPCR-Script™ Amp SK(+) vector in the presence of Srf-1 enzyme and the ligation reaction products were transformed into the XL-10 Gold™ Kan ultracompetent E. coli cells. Selection for transformation with plasmids containing inserts was done using LB-Amp plates

and IPTG and Xgal spread on the surface as described in the pPCR-ScriptTM Amp kit. White colonies were selected and the clones were named Dav1-1 etc.

Production of Second Set of seed cDNA clones with Size Selected cDNA

5 Seeds highly express a small number of proteins, such as the seed storage proteins (White *et al*, 2000, Plant Physiology, Vol 124, 1582-1594). When cDNA is prepared from such tissue, the very high level of the storage proteins and other seed specific proteins leads to a high level of cDNA “redundancy”, that is, the population of cDNA produced contains high proportions of the same cDNA. In order to reduce the redundancy of cDNA made from
10 coffee seed mRNA, and to selectively characterise long and weakly expressed cDNA, a second cDNA cloning strategy was also used. Using the products of the reverse transcriptase reaction described above, the following PCR reactions was set up using the AdvantageTM 2 PCR kit (ClonTech): 3 µL of the reverse transcriptase reaction, 5 µL 10 x AdvantageTM 2 PCR buffer, 1 µL dNTP's (10 mM each), 2 µL PCR primer (SMARTTM PCR cDNA kit,
15 Clontech), 39 µL deionised water, and 1 µL 50 x AdvantageTM 2 polymerase mix. This PCR reaction was then placed in a MJ Research PTC-150 HB apparatus and the following PCR conditions were run: 95°C for 1 minute, then 16 cycles of 95°C for 15 seconds, 65°C for 30 seconds, 68°C for 6 minutes. At the end of the PCR, 1 µL 10% SDS was added with gel loading buffer, the sample was heated to 37°C for ten minutes. The sample was then split for
20 loading onto a 0.7% agarose gel without ethidium bromide: 10% was loaded into a small well beside a DNA marker lane and the other 90% was loaded into a neighbouring large, preparation scale well. After the gel was run, the gel section with the size markers, plus the 10% reaction sample, were stained with ethidium bromide. This stained gel section was then used as a template to generate gel slices containing PCR amplified cDNA of different sizes
25 from the cDNA present in the remaining unstained (preparation) part of the gel. Six gel slices were generated having the indicated size range of PCR fragments; A1A (0.8-1kb), A1B (1-1.5 kb), A2 (1.5-2.25 kb), A3 (2.25-3.25), A4 3.25-4 kb), and A5 (4-6.5 kb).

The DNA in each gel slice was eluted from the agarose using the QIAEX II kit from Qiagen
30 following the suppliers instructions (for samples 3A, 4A, and 5A were heated for 10 minutes at 50°C and 1A, 1B, and 2A were heated for 10 minutes at room temperature). The purified double stranded cDNA was then re-amplified further by PCR with a TAQ enzyme mix which makes fragments having a 3' T overhang as follows: 30 µL of the gel isolated double

stranded cDNA, 5 µL 10 x TAQ buffer (supplied with TAQ PLUS precision polymerase mix, Stratagene), 1 µL 40 mM dNTP's (each 10 mM), 2 µL PCR primer (SMART™ PCR cDNA kit, Clontech), 0.5 µL TAQ PLUS precision polymerase mix (Stratagene) and 11.5 µL deionised water. The PCR reaction conditions were as follows: 95°C for 1 minute then 7 cycles 95°C for 15 seconds, 65°C for 1 minute, 72°C for 8 minutes, then 1 cycle at 95°C for 15 seconds, 65°C for 1 minute, 72°C for 10 minutes.

The PCR amplified DNA produced was then ligated into the vector pCR™-TOPO™ and cloned into TOP10 *E. coli* cells using the TOPO™ TA kit (Invitrogen) as described by the supplier. The clones were named by their order of isolation and their position in the sizing gel (for example, A2-1, A2-2, etc.).

Seed cDNA Screening and Preliminary Identification

The first set of white colonies obtained in Dav-1 library were screened by first determining the size of each insert by PCR amplifying the insert using the primers T3 and T7 which flank the cloning site used and examining the PCR amplified fragments on a gel.

Each white colony were resuspended in 200 µl sterile water and 10-30 µl of this was added to 5 µl 10X Taq polymerase buffer (Stratagene), 1 µl 10 mM dNTP mix, 2.5 µl 20 µM T3 primer, 2.5 µl 20 µM T7 primer, 1 µl DMSO, 0.5 µl Taq polymerase (Stratagene), and H₂O up to 50 µl final volume). The PCR reaction program uses was 94°C for 1 min, then 30 cycles of 94°C for 1 min, 55°C for 1.5 min and 3.5 min at 72°C, and a final cycle of 7 min at 72°C. To reduce redundancy, the PCR inserts of similar size were subjected to digestion by the restriction enzyme Hae III. Those PCR fragments with the same Hae III restriction pattern were not studied further. The plasmids of clones with PCR fragments >500 bp and which had unique Hae III restriction patterns were then purified by using the Qiawall 8 ultra plasmid kit (Qiagen) for 5' end dideoxy sequencing using the appropriate T7 or T3 sequencing primers coded in the flanking vector sequences. Because the inserts were not cloned in a directed fashion, it was first necessary to determine the 5' end of each clone by a ScaI digestion of the purified plasmid DNA (the CDS SMART primer contains a Sca I site allowing the orientation of the insert to be determined). The DNA sequence data obtained was subsequently blasted against the non-redundant database protein in GENE BANK to obtain a preliminary annotation of each cDNA clone using the program BLASTX™.

Seed cDNA banks have a high level of redundancy. That is, a small number of seed mRNA have an unusually high level of expression, such as those encoding the seed storage proteins, and therefore their cDNA are very abundant in seed cDNA banks (White *et al*, 2000, Plant Physiology, Vol 124, 1582-1594). Therefore, as soon as the main redundant cDNA's were identified in the first round of sequencing the coffee seed cDNA, a pre-screening step was added for the white insert containing colonies prior to the determination of insert size. Four sequences were very highly expressed and the following specific primers sets were made for each of these redundant sequences,

10 1) 2S protein, contig 8A 5' AGCAACTGCAGCAAGGTGGAG 3' and contig 8B 5'
CGATTGGCACTGCTGTGGTTC 3' (55°C used in PCR, 114 bp fragment),
2) 2S protein contig 15A 5' GCCCGTGCTCCTGAACCA 3' and contig 15B 5'
GTATGGTTGCGGTGGCTGAA 3' (55°C used in PCR, 256 bp fragment),
3) Oleosin 15.5 contig 30A 5' ACCCCGCTTTCGTTAT 3' and contig 30B
15 TCTGGCTACATCTTGAGTTCT 3' (55°C used in PCR, 261 bp fragment), and
4) 11S protein contig 37A 5' GTTTCCAGACCGGCCATCAG 3' and contig 37B 5'
ATATCCATCCTCTTCCAACACC 3' (59°C used in PCR, 261 bp fragment).

20 The PCR reactions for this prescreen step were run as follows: 10-30 µl of the white colony in sterile H₂O, 5 µl 10X Taq buffer (Stratagene), 1 µl 10 mM dNTP, 2.5 µl of each primer at 20 µM, 1 µl DMSO, 0.5 µl Taq polymerase (Stratagene 10U/µl) and sterile H₂O was added to produce a final reaction total volume of 50 µl. The PCR program was 1 min at 94°C, then 30 cycles of 1 min at 94°C, 1.5 min at specific temperature for each primer pair, 2.5 min at 72°C, followed by 7 min at 72°C.

25 Full Length cDNA Insert Sequencing and Sequence Analysis
cDNA clones whose partial sequences showed initial homologies to proteinases and proteinase inhibitors were fully sequenced on both strands using the standard dideoxy primer walking strategy. The sequences are shown under SEQ ID Nos. 1, 3, 5 and 7. The full length 30 sequences obtained were again blasted against the GenBank non redundant protein database using BLASTX to reinforce the preliminary annotation

Sequence identities of sequence pairs were calculated using the ClustalW™ program contained in the MegAlign™ module of the Lasergene™ software package (DNASTAR Inc). The default parameters were chosen as follows: (1- MULTIPLE ALIGNMENT PARAMETERS - Gap penalty 15.00, Gap length penalty 6.66, Delay divergent Seqs (%) 30, 5 DNA transition weight 0.5, Protein Weight Matrix-Gonnet Series, DNA Weight Matrix IUB. 2- PAIRWISE ALIGNMENT PARAMETERS-Slow/Accurate (Gap Penalty 15.00, Gap Length Penalty 6.66), Protein Weight Matrix-Gonnet 250, DNA Weight Matrix-IUB) and the sequences used were either the full length nucleotide sequence of each cDNA or the full ORF (open reading frame) of each cDNA.

10

TABLE 2

Identity values between the nucleic acid and amino acid sequences of CcCP-1, CcCPI-1, and CcAP-2 and related genes found in the non-redundant protein database of GeneBank and 15 those of WO 02/04617.

cDNA Sequences	nucleotide identity (%)	protein identity (%) (ORF)
CcAP1 vrs TcAP1	2.9	13.3
CcAP1 vrs TcAP2	2.4	9.8
CcAP2 vrs TcAP1	55.0	61.5
CcAP2 vrs TcAP2	55.1	61.3
CcCP-1 vs <i>Arabidopsis thaliana</i> putative cysteine proteinase (AY070063)	51.8	64.3
CcCP-1 vs <i>Glycine max</i> cysteine endopeptidase (Z32795)	49.1	61.3
CcCP-1 vs <i>Vicia sativa</i> cysteine proteinase precursor (Z99172)	49.0	60.9
CcAP2 vs <i>Lycopersicon esculentum</i> aspartic proteinase precursor (L46681)	65.9	71.1
CcAP2 vs <i>Ipomoea batatas</i>		

putative aspartic proteinase mRNA (AF259982)	71.7	69.6
CcAP2 vs <i>Nepenthes alata</i> NaAP4 mRNA for aspartic proteinase 4 (AB045894)	58.4	66.5
CcCPI-1 vs <i>Malus x domestica</i> cystatin (AY176584)	38.8	45.5

Northern-Blot Analysis

5

Freshly harvested roots, young leaves, stem, flowers and fruit at different stages of development (small green fruit (SG), large green fruit (LG), Yellow fruit (Y) and red fruit (R)) were harvested from *Coffea arabica* var. Catura T-2308 grown under greenhouse conditions (25°C, 70 RH) in Tours, France, and from *Coffea canephora* var. BP409 grown either in Ecuador or ICCRI, Indonesia. The fresh tissues were frozen immediately in liquid nitrogen and total RNA was isolated from each tissue using the extraction procedure described above. A total of 5 µg of RNA was run on a 1.2% (w/v) denaturing RNA gel containing formaldehyde. The total RNA samples from each plant tissue were heated at 65°C for 15 min in presence of 7 µL "RNA Sample Loading Buffer" (without ethidium bromide, Sigma), and then put immediately on ice for 2 minutes before being loaded onto the 1.2% RNA gel. The gels were run at 60 Volts for 5 hours. The gel was then soaked twice in 10× SSC for 20 min. The RNA in the gel was transferred overnight by capillary transfer to a "Positive TM Membrane" (Qbiogene) in 10× SSC and the RNA was fixed by heating the blot for 30min at 80°C. Probes were generated using "Rediprime™ II random prime labelling system" kit (Amersham) in the presence of (P^{32}) dCTP. Hybridisation was carried out at 65°C for 24 h in hybridisation solution (5X SSC, 40µg/ml Denatured Salmon Sperm DNA, 5% [w/v] SDS, and 5× Denhardt's solution). Then, the membrane was washed twice at 65°C using 2X SSC, 0.1% SDS [w/v] and 1X SSC, 0.1% SDS [w/v] during 30 minutes each.

25 5' RACE PCR

The cDNA insert of clone A5-812 was found to contain introns. Therefore, to confirm the coding sequence of this protein, it was necessary to isolate a new cDNA containing the complete coding sequence. This was accomplished by using the SMART™ RACE cDNA amplification Kit (Clontech). The first strand cDNA used for the 5' RACE was made as 5 already described for the cDNA libraries above. A gene specific primer rAP2 (5'
CATATAATATTAAAAGCACCACCCATAA 3') was designed - this sequence is situated 92 pb from the poly (A) tail of A5-812 clone. This specific primer was then used with the Universal Primer Mix (UPM) in the CLONTECH kit in a PCR reaction under the following conditions; 2.5 µl of first strand cDNA product, 5 µl of 10X Advantage 2 PCR Buffer
10 (CLONTECH), 1 µl of dNTP Mix (10 mM), 1 µl of 50X Advantage 2 Polymerase Mix (CLONTECH), 5 µl of "Universal Primer A Mix" (10X) (CLONTECH), 1 µl of rAP2 (10 µM) and sterile water was added to a final volume of 50 µl. PCR cycling conditions were 20 cycles of 30 sec at 94°C, 30 sec at 68°C and 3 min at 72°C, followed by a final extension reaction for 5 min at 72°C. A fragment of about 1700 pb was obtained, excised from the gel
15 using "CONCERT™ Rapid Gel Extraction kit" (GibcoBRL). The isolated fragment was cloned in the pCR 4-TOPO vector and transformed into Escherichia coli using the Topo-TA cloning kit (Invitrogen). The plasmid obtained was then purified using a plasmid extraction kit (QIAfilter Plasmid Midi Kit, Qiagen, France) and the insert of this plasmid was double strand sequenced.
20

The DNA of clone A5-442 (AP1) was found to lack the 5' region of the cDNA. To isolate this region a 5' RACE was performed using the SMART™ RACE cDNA amplification Kit (Clontech). A sequence specific primer rAP1 (5'-
TGGAGTCACAAGATGTCTCGACGAACTG-3') situated at 396 pb from the poly (A) tail
25 was designed. This specific primer was then used with the Universal Primer Mix (UPM) in the CLONTECH kit in a PCR reaction under the following conditions; 2.5 µl of first strand cDNA, 5 µl of 10X Advantage 2 PCR Buffer (CLONTECH), 1 µl of dNTP Mix (10 mM), 1 µl of 50X Advantage 2 Polymerase Mix (CLONTECH), 5 µl of "Universal Primer A Mix" (10X) (CLONTECH), 1 µl of rAP1, and sterile water was added to a final volume of 50 µl.
30 PCR cycling conditions were 20 cycles of 30 sec at 94°C, 30 sec at 68°C and 3 min at 72°C, followed by a final extension reaction for 5 min at 72°C. A fragment of about 2,000 bp was obtained, excised from the gel using "CONCERT™ Rapid Gel Extraction kit" (GibcoBRL). The isolated fragment was cloned in the pCR 4-TOPO vector and transformed into

Escherichia coli using the Topo-TA cloning kit (Invitrogen). The plasmid obtained was then purified using a plasmid extraction kit (QIAfilter Plasmid Midi Kit, Qiagen, France) and the insert of this plasmid was double strand sequenced.

5 The Northern blot analysis shown in Figure 1 demonstrates that the coffee cysteine proteinase gene CcCP-1 gene is expressed in the *C. arabica* coffee cherry at all the stages tested, with yellow cherries exhibiting slightly higher levels of expression than the other stages. No expression was detected for this gene in the root, stem or leaves of *C. arabica*.

10 The Northern blot analysis shown in Figure 2 demonstrates that the coffee cysteine proteinase inhibitor gene CcCPI-1 gene is expressed in the *C. arabica* coffee cherry at all stages tested. However, in contrast to the expression seen for the cysteine proteinase CcCP-1, CcCPI-1 exhibits higher expression in the two early stages of coffee cherry development (small green and large green), and this gene is expressed at lower levels in the two later stages of cherry

15 development. This expression pattern is consistent with the present hypothesis that the cysteine proteinase inhibitor protein (CcCPI-1) controls the activity level of the cysteine proteinase CcCP-1 in the coffee cherry. A controlling protein such as the cysteine proteinase inhibitor protein can be expected to be expressed earlier than its target protein if it is necessary to control the level of activity of its target protein continuously from the time that

20 the target protein is expressed. No expression was detected for this gene in the root, stem or leaves of *C. arabica*. It is noted that the similarity of the expression patterns for CcCP-1 and CcCPI-1 are consistent with the present hypothesis that these proteins interact functionally.

25 The Northern blot analysis shown in Figure 3 demonstrates that the coffee cysteine proteinase inhibitor gene CcCPI-1 gene is expressed differently in the cherries of *C. canephora* (robusta) versus the cherries of *C. arabica*. First, the data of Figure 3 shows that the CcCPI-1 gene is expressed slightly earlier in *C. arabica*. Secondly, and more importantly, the CcCPI-1 gene is expressed in significantly higher levels in the *C. canephora* cherries. This difference in expression probably affects the level of the cysteine proteinase activity found in *C. arabica*

30 versus *C. canephora* cherries. Because this class of protein is widely associated with insect resistance in plants, it is also likely that the high expression of the CcCPI-1 gene in *C. canephora* contributes to the higher disease resistance often seen for robusta varieties versus arabica varieties.

The Northern blot analysis shown in Figure 4 demonstrates that the coffee aspartic proteinase CcAP-2 gene is expressed in both the grain and the pericarp of the *C. arabica* coffee cherry at all cherry development stages tested. The CcAP-2 gene also has a relatively high expression in roots. When the film is exposed longer, CcAP-2 expression was also detected in the
5 tissues of *C. arabica* stems, leaf, and flowers.

Overexpression and under-expression of the CcCP-1, CcAP-1 and CcAP-2 proteinase gene sequences and the CcCPI-1 proteinase inhibitor in coffee seeds.

It is expected that the major storage protein profile and the amino acid peptide profile can be
10 changed in the mature coffee grain by altering, either up or down, the expression of one or more of the genes disclosed herein.

Methods for the overexpression of a gene of interest are well known in the art. Such methods consist of creating a chimeric gene of three major components, 1) a promoter sequence at the
15 5' end of the gene, preferably in the current application a seed specific promoter such the coffee seed specific promoter described in Marrachini et al. 1999 (Marraccini et al 1999 Molecular cloning of the complete 11S seed storage protein gene of *Coffea arabica* and promoter analysis in transgenic tobacco plants, Plant Physiol. Biochem. Vol 37, 273-282, and WO 99/02688), 2) the entire coding sequence of the gene to be expressed, and 3) a 3' control
20 region such as the 3' region from the nopaline synthase gene from the T-DNA of the Ti plasmid of *Agrobacterium tumefaciens*. Then, the chimeric gene can be cloned into an *Agrobacterium tumefaciens* transformation vector, and this vector can be transformed into an *Agrobacterium tumefaciens* strain for use in coffee transformation as described by Leroy et al 2000, (Leroy et al 2000 Genetically modified coffee plants expressing the *Bacillus*
25 *thuringiensis* cry1Ac gene for resistance to leaf minor. Plant Cell Reports 2000, 19, 382-389). Plants with stable transformation inserts can then be screened for those which overexpress the specific genes used in the transformation experiment specifically in mature seeds using methods such as detection of gene overexpression or protein activity overexpression versus seeds from mock transformed plants.
30

It is well known in the art that the expression of known gene sequences can be reduced or completely blocked by antisense suppression and of gene expression using nucleic acid fragments representing less than the entire coding region of a gene, and by nucleic acids that do not share 100% sequence identity with the gene to be suppressed. In this case, the

sequences chosen for the particular antisense suppression or cosuppression experiment will replace the full length gene in the chimeric gene construction scheme presented above. The resulting antisense suppression or cosuppression chimeric constructions are again cloned into an *Agrobacterium tumefaciens* transformation vector, and transformed into *Agrobacterium tumefaciens* strain for use in coffee transformation as described above. Plants with stable transformation inserts can then be screened for those with reduced expression of the specific gene sequences used in the seeds of the transformed plants. The reduced expression can be detected by techniques such as northern blotting ;semi quantitative RT-PCR, and/or quantitative RT-PCR.

10

Another method for reducing, or eliminating, the expression of a gene in plants is to use the small portions of the gene sequences disclosed herein to produce RNA silencing via using RNAi (Hannon, G.J., 2002, Nature, Vol 418, 244-251; Tang *et al*, 2003, Genes Dev, Vol 17, 49-63). In this approach, small regions of one or more of the sequences disclosed herein are cloned into an *Agrobacterium tumefaciens* transformation vector as described above which has a seed specific promoter and an appropriate 3' regulatory region. This new inserted sequence for RNAi should be constructed so that the RNA produced forms an RNA structure *in vivo* which result in the production of small double stranded RNA in the transformed cells and whereby these small double stranded RNA sequences trigger the degradation of the homologous mRNA in these transformed cells.

20
25
Screening for naturally occurring variations in the CcCP-1, CcAP-1, CcAP-2, CcCPI-1 genes and creating new mutations in these genes.

The sequences disclosed herein can be used to screen natural populations for allelic variants in these genes. This can be accomplished by using the CcCP-1, CcAP-2, CcCPI-1 sequences as probes in a search for naturally occurring RFLP's (restriction fragment length polymorphisms) in genomic DNA from different coffee plant varieties. A more powerful method to find allelic variants is to use the mutation screening technology associated with the TILLING method (Till, B.J., *et al* 2003 Large scale discovery of induced point mutations with high-thruput TILLING. Genome Research Vol 13, 524-530). In this case, once a specific gene sequence has been isolated and cloned, such as CcCP-1, CcAP-2, CcCPI-1 sequences herein, the mutation screening technique associated with the TILLING method can be used to identify sequence variants between the cloned sequence and the corresponding cDNA or genomic sequence in different varieties. Using PCR primer pairs coding for DNA

segments of 700-1100 base pairs, the known cloned gene can be scanned for naturally occurring sequence variations in different varieties. In the ideal situation, one or more sequence variants could also be correlated with a particular phenotypic variation thereby identifying a genetic marker for this phenotypic variant.

5

Additionally, using the sequences disclosed herein for CcCP-1, CcAP-2 and CcCPI-1, application of the full TILLING method can be used to create and detect new mutants in these genes and thus produce plants containing these specific mutants. For example, using the full TILLING method, coffee plants could be created which have specific mutations, such 10 as a missense mutation in the coding sequence which inactivates the gene target of interest.

CLAIMS:

1. An isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having cysteine proteinase activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 2 have at least 70%, preferably at least 80%, sequence identity based on the ClustalW alignment method; or the complement of the nucleotide sequence, wherein the complement contains the same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary.
5
- 10 2. The polynucleotide of Claim 1, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 2 have at least 85%, preferably at least 90%, optionally at least 95%, sequence identity based on the ClustalW alignment method.
- 15 3. The polynucleotide of Claim 1, wherein the nucleotide sequence comprises the nucleotide sequence of SEQ ID No. 1.
- 20 4. The polynucleotide of Claim 1, wherein the polypeptide comprises the amino acid sequence of SEQ ID No. 2.
- 25 5. An isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having cysteine proteinase inhibitor activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 4 have at least 70%, preferably at least 80%, sequence identity based on the ClustalW alignment method; or the complement of the nucleotide sequence, wherein the complement contains the same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary.
- 30 6. The polynucleotide of Claim 5, wherein the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID No. 4 have at least 85%, preferably at least 90%,
~~optionally at least 95%~~, sequence identity based on the ClustalW alignment method.
100% sequence identity

7. The polynucleotide of Claim 5, wherein the nucleotide sequence comprises the nucleotide sequence of SEQ ID No. 3.
8. The polynucleotide of Claim 5, wherein the polypeptide comprises the amino acid sequence of SEQ ID No. 4.
9. An isolated polynucleotide comprising a nucleotide sequence encoding a polypeptide having aspartic endoproteinase activity, wherein the amino acid sequence of the polypeptide and the amino acid sequence selected from SEQ ID No. 6 or 8, preferably SEQ ID No. 8, have at least 75%, preferably at least 80%, sequence identity based on the ClustalW alignment method, or the complement of the nucleotide sequence, wherein the complement contains the same number of nucleotides as the nucleotide sequence, and the complement and the nucleotide sequence are 100% complementary.
10. The polynucleotide of Claim 9, wherein the amino acid sequence of the polypeptide and the amino acid sequence selected from SEQ ID No. 6 or 8, preferably SEQ ID No. 8, have at least 85%, preferably at least 90%, optionally at least 95%, sequence identity based on the ClustalW alignment method.
11. The polynucleotide of Claim 9, wherein the nucleotide sequence comprises the nucleotide sequence of SEQ ID No. 5 or 7, preferably SEQ ID No. 7.
12. The polynucleotide of Claim 9, wherein the polypeptide comprises the amino acid sequence of SEQ ID No. 6 or 8, preferably SEQ ID No. 8.
13. A vector comprising the polynucleotide of any one of Claims 1 to 12.
14. A recombinant DNA construct comprising the polynucleotide of any one of Claims 1 to 12 operably linked to a regulatory sequence.
15. A method for transforming a cell comprising transforming a cell with the polynucleotide of any one of Claims 1 to 12.
16. A cell comprising the recombinant DNA construct of Claim 14.

17. The cell of Claim 16, which is a prokaryotic cell, an eukaryotic cell or a plant cell, preferably a coffee cell.
- 5 18. A transgenic plant comprising the cell of Claim 16 or 17.
19. A method for modulating coffee flavour precursor levels in green coffee grains, the method comprising introducing into the coffee plant the recombinant DNA construct of Claim 14.

Abstract

Modulation of Coffee Flavour Precursor Levels in Green Coffee Grains

5 The present invention relates to isolated polynucleotides encoding cysteine proteinases; cysteine proteinase inhibitors; and aspartic endoproteeinases.

The invention also relates to a transformed host cell, preferably a plant cell, in which over- or under-expression of these polynucleotides result in altered levels of coffee flavour precursor

10 levels, specifically, amino group-containing molecules such as amino acids, peptides and proteins, in green coffee grains.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- BLACK BORDERS**
- IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- FADED TEXT OR DRAWING**
- BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- SKEWED/SLANTED IMAGES**
- COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- GRAY SCALE DOCUMENTS**
- LINES OR MARKS ON ORIGINAL DOCUMENT**
- REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
